It is a tool that, by storing transportation data, can be used as a transportation management system and also a transportation decision support tool. TransCAD is available as a desktop program for Linux, Windows and Mac systems. TransCAD Server is a GIS system that allows users with a desktop or laptop computer to access and store transportation data using web browser clients. TransCAD Server is available as a Linux, Windows, and Mac-compatible package. The TransCAD system provides, among other things: Web-based desktop client (Windows, Linux, and Mac) Windows, Linux and Mac versions of the TransCAD Desktop GIS software A PC based GIS server, running on either Windows, Linux or Mac The ability to build and store routes with junction or leg style routings. Transportation data and parameters can be inserted from any major transportation software package. Access the transportation data and parameters using an easily interpretable format. Display the data and parameters in a way that is easily understandable to transportation decision makers and transportation planners. TransCAD provides a dynamic route planner that will create multiple alternative routes. The routes are planned for a specific criterion such as minimizing cost, time, or traffic. Routes are planned using a graph based navigation system. This system allows users to select and modify routes, and return to the route planning stage and make new routes until the final route is generated. An additional route is added to the route planner by adding additional edges to the graph. The route planner uses the edge added data in a calculation to determine the path or route best suited to the specified criterion. Features Editing TransCAD includes the ability to edit the route generation rules for the route planner. As the data and parameters are entered into the TransCAD system the route planner will be updated with the new information. As new data is added to TransCAD or if data is changed the route planner will be updated with the new information. As data is updated or changed the route planner will recalculate the route and return to the route planning stage. Data types TransCAD uses the following data types: Route points Route lines Route parameters Route Points Route Points represent locations on the route. These locations can be created by using multiple data types such as points, blocks, and polygons. Route points are named by the 82157476af
